There are many ways to contribute towards humanity. Helping each other is one of them, but specifically, protecting the youth is one of those that often feels like a duty. The things they experience or lack of, can go on to affect them for the rest of their lives. The earliest memory of me realising it's something I'm passionate about is when I volunteered for math tutoring at my school. One section had a student with autism significantly struggling, and the teacher couldn't accommodate the extra attention he required. After a few lessons together, it was clear he was capable of learning and only struggled with the environment and low confidence. I only played a tiny role there, but you never know the impact these things have.

I'm actually working on my master's thesis right now on AI moderation of social media comments, which was inspired by the youth social media ban in Australia. To summarise, I feel as if all of the new generation is "groomed" by the internet to some degree. Hoping the DSA legislation imposes higher requirements on these platforms due to the harm they cause the youth. This doctoral position will be a lot more focused on building tools and methods to equip the field, but I think we can find a common motivation of wanting change for the betterment of the youth.

On the topic of tech-related skills, I believe I have them covered quite well. I've worked with LLMs, finetuning them, RAG and other NLP tasks like classification problems. Aside from my thesis, I've worked also worked on my own startup idea for finding relevant research papers and patents for R&D departments. My bachelor's was in software engineering, so I'm comfortable wth coding practices. My cloud and ops-related skills are the weakest, as I've only recently learnt and applied them in a project with a company in Uppsala last semester.

On the domain side of things, I've taken special interest in healthcare before and after coming to Sweden. From the research competition manuscript I've attached on health insurance, to multiple small projects with hospitals (CSICU procedure KPI dashboard and Akutmottagning demand prediction), I have a decent understanding of public health without a formal education. Then I've taken courses such as Designing Health Innovations to learn more about the legal aspect of healthtech in Sweden, along with IT & Society, which was a large project in collaboration with a healthtech startup working on EHR data and usability. I'm happy to share more in person, but essentially, I'm familiar with how to deal with AI, data and legislation. I actually attended an AI Act conference through the lens of healthcare in Uppsala with a researcher, as we were working on a project proposal on measuring medical AI fairness at the time.

I do not have a background in epidemiology or systematic review methodology. I hope the rest of my experience qualifies me. One other reason I'm applying to the position is that I'm undecided if I'll remain in academia afterwards. I'm sure the 4 years will help me decide, but the fact that I'm developing open-source tools in very relevant tech fields keeps the industry option quite open for me after completion. I look forward to a chance to discuss the specifics of the project, meet the team and learn a bit more about the collaboration between the research groups and other bodies. Essentially, what are we doing to ensure we build the right methods that will actually be utilised by various actors and not sit on the shelf.
